

FEATURES

SFP/SFF and SFF-8472 MSA-compliant
SFP reference design available
50 Mbps to 3.3 Gbps operation
Multirate 155 Mbps to 3.3 Gbps operation
Dual-loop control of average power and extinction ratio
Typical rise/fall time 60 ps
Bias current range 2 mA to 100 mA
Modulation current range 5 mA to 90 mA
Laser fail alarm and automatic laser shutdown (ALS)
Bias and modulation current monitoring
3.3 V operation
4 mm × 4 mm LFCSP package
Voltage setpoint control
Resistor setpoint control

APPLICATIONS

Multirate OC3 to OC48-FEC SFP/SFF modules
1×/2×/4× Fibre channel SFP/SFF modules
LX-4 modules
DWDM/CWDM SFP modules
1GE SFP/SFF transceiver modules

GENERAL DESCRIPTION

The ADN2870 laser diode driver is designed for advanced SFP and SFF modules, using SFF-8472 digital diagnostics. The device features dual-loop control of the average power and extinction ratio, which automatically compensates for variations in laser characteristics over temperature and aging. The laser need only be calibrated at 25°C, eliminating the need for expensive and time consuming temperature calibration. The ADN2870 supports single-rate operation from 50 Mbps to 3.3 Gbps or multirate from 155 Mbps to 3.3 Gbps.

Average power and extinction ratio can be set with a voltage provided by a microcontroller DAC or by a trimmable resistor. The part provides bias and modulation current monitoring as well as fail alarms and automatic laser shutdown. The device interfaces easily with the ADI ADuC70xx family of micro-converters and with the ADN289x family of limiting amplifiers to make a complete SFP/SFF transceiver solution. An SFP reference design is available. The product is available in a space-saving 4 mm × 4 mm LFCSP package specified over the -40°C to +85°C temperature range.

θ_{JC} Thermal Impedance	29.5°C/W
Lead Temperature (Soldering 10 s)	300°C

¹ Power consumption equations are provided in the Power Consumption section.

² θ_{JA} is defined when part is soldered on a 4-layer board.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

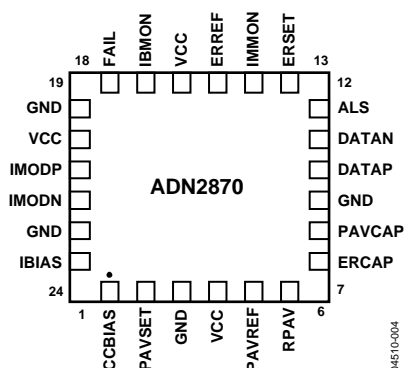

Figure 5. Pin Configuration

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	CCBIAS	Control Output Current
2	PAVSET	Average Optical Power Set Pin

Operation with Lasers with Temperature-Dependent Nonlinearity of Laser LI Curve

The ADN2870 ERCL extracts information from the monitor photodiode signal relating to the slope of the LI characteristics at the optical 1 level (P1). For lasers with good linearity over temperature, the slope measured by the ADN2870 at the optical 1 level is representative of the slope anywhere on the LI curve. This slope information is used to set the required modulation current to achieve the required optical extinction ratio.

Figure 25. Measurement of a Laser LI Curve Showing Laser Nonlinearity at High Temperatures

Some types of laser have LI curves that become progressively more nonlinear with increasing temperature (see Figure 25). At temperatures where the LI curve shows significant nonlinearity, the LI curve slope measured by the ADN2870 at the optical 1 level is no longer representative of the overall LI curve. It is evident that applying a modulation current based on this slope information cannot maintain a constant extinction ratio over temperature. However, the ADN2870 can be configured to maintain near constant optical bias and extinction ratio with a laser exhibiting a monotonic temperature-dependant nonlinearity. To implement this correction, it is necessary to characterize a small sample of lasers for their typical nonlinearity by measuring them at two temperature points, typically 25°C and 85°C. The measured nonlinearity is used to determine the amount of feedback to apply. Typically one must characterize 5 to 10 lasers of a particular model to get a good number. Then the product can be calibrated at 25°C only, avoiding the expense of temperature calibration. Typically the microcontroller supervisor is used to measure the laser and apply the feedback. This scheme is particularly suitable for circuits that already use a microcontroller for control and digital diagnostic monitoring.

The ER correction scheme, while using the average nonlinearity for the laser population, in fact, supplies a corrective measurement based on each laser's actual performance as measured during operation. The ER correction scheme corrects for errors due to laser nonlinearity while the dual loop continues to adjust for changes in the Laser LI.

For more details on maintaining average optical power and extinction ratio over temperature when working with lasers displaying a temperature dependant nonlinearity of LI curve, see Application Note AN-743.

CONTROL

The ADN2870 has two methods for setting the average power (PAV) and extinction ratio (ER). The average power and extinction ratio can be voltage-set using a microcontroller's voltage DACs outputs to provide controlled reference voltages PAVREF and ERREF. Alternatively, the average power and extinction ratio can be resistor-set using potentiometers at the PAVSET and ERSET pins, respectively.

VOLTAGE SETPOINT CALIBRATION

The ADN2870 allows interface to a microcontroller for both control and monitoring (see Figure 26). The average power at the PAVSET pin and extinction ratio at the ERSET pin can be set using the microcontroller's DACs to provide controlled reference voltages PAVREF and ERREF. Note that during power up, there is an internal sequence that allows 25 ms before enabling the alarms; therefore the customer must ensure that the voltage for PAVREF and ERREF are active within 20 ms.

$$PAVREF = P_{AV} \times R_{SP} \times R_{PAV} \text{ (Volts)}$$

$$ERREF = R_{ERSET} \times \frac{I_{MPD_CW}}{P_{CW}} \times \frac{ER - 1}{ER + 1} \times P_{AV} \text{ (Volts)}$$

where:

R_{SP} is the monitor photodiode responsivity.

P_{CW} is the dc optical power specified on the laser data sheet.

I_{MPD_CW} is MPD current at that specified P_{CW} .

P_{AV} is the average power required.

ER is the desired extinction ratio ($ER = P1/P0$).

In voltage setpoint, R_{PAV} and R_{ERSET} must be 1 kΩ resistors with a 1% tolerance and a temperature coefficient of 50 ppm/°C.

[illegible]

Rev. 0 | Page 13 of 20

RESISTOR SETPOINT CALIBRATION

In resistor setpoint calibration, PAVREF, ERREF, and RPAV must all be tied to VCC. Average power and extinction ratio can be set using the PAVSET and ERSET pins, respectively. A resistor is placed between the pin and GND to set the current flowing in each pin as shown in Figure 27. The ADN2870 ensures that both PAVSET and ERSET are kept 1.2 V above GND. The PAVSET and ERSET resistors are given by the following:

$$R_{PAVSET} = \frac{1.23 \text{ V}}{P_{AV} \times R_{SP}} (\Omega)$$

$$R_{ERSET} = \frac{1.23 \text{ V}}{\frac{I_{MPD_CW}}{P_{CW}} \times \frac{ER-1}{ER+1} + P_{AV}} (\Omega)$$

where:

R_{SP} is the monitor photodiode responsivity.

P_{CW} is the dc optical power specified on the laser data sheet.

I_{MPD_CW} is MPD current at that specified P_{CW} .

P_{AV} is the average power required.

ER is the desired extinction ratio ($ER = P1/P0$).

IMPD MONITORING

IMPD monitoring can be implemented for voltage setpoint and resistor setpoint as follows.

Voltage Setpoint

In voltage setpoint calibration, the following methods may be used for IMPD monitoring.

Method 1: Measuring Voltage at RPAV

The IMPD current is equal to the voltage at RPAV divided by the value of RPAV (see Figure 28) as long as the laser is on and is being controlled by the control loop. This method does not provide a valid IMPD reading when the laser is in shut-down or fail mode. A microconverter buffered A/D input may be connected to RPAV to make this measurement. No decoupling or filter capacitors should be placed on the RPAV node because this can disturb the control loop.

Figure 28. Single Measurement of IMPD RPAV in Voltage Setpoint Mode

Method 2: Measuring IMPD Across a Sense Resistor

The second method has the advantage of providing a valid IMPD reading at all times, but has the disadvantage of requiring a differential measurement across a sense resistor directly in series with the IMPD. As shown in Figure 29, a small resistor, R_x , is placed in series with the IMPD. If the laser used in the design has a pinout where the monitor photodiode cathode and the lasers anode are not connected, a sense resistor can be placed in series with the photodiode cathode and VCC as shown in Figure 30. When choosing the value of the resistor, the user must take into account the expected IMPD value in normal operation. The resistor must be large enough to make a significant signal for the buffered A/Ds to read, but small enough so as not to cause a significant voltage reduction across the IMPD. The voltage across the sense resistor should not exceed 250 mV when the laser is in normal operation. It is recommended that a 10 pF capacitor be placed in parallel with the sense resistor.

Figure 29. Differential Measurement of IMPD Across a Sense Resistor

Figure 30. Single Measurement of IMPD Across a Sense Resistor

Resistor Setpoint

In resistor setpoint calibration, the current through the resistor from PAVSET to ground is the IMPD current. The recommended method for measuring the IMPD current is to place a small resistor in series with PAVSET resistor (or potentiometer) and measure the voltage across this resistor as shown in Figure 31. The IMPD current is then equal to this voltage divided by the value of resistor used. In resistor setpoint, PAVSET is held to 1.2 V nominal; it is recommended that the sense resistor should be selected so that the voltage across the sense resistor does not exceed 250 mV.

Figure 31. Single Measurement of IMPD Across a Sense Resistor in Resistor Setpoint IMPD Monitoring

LOOP BANDWIDTH SELECTION

To ensure that the ADN2870 control loops have sufficient bandwidth, the average power loop capacitor (PAVCAP) and the extinction ratio loop capacitor (ERCAP) are calculated using the lasers slope efficiency (watts/amps) and the average power required.

For resistor point control:

$$PAVCAP = 3.2E - 6 \times \frac{LI}{PAV} \text{ (Farad)}$$

$$ERCAP = \frac{PAVCAP}{2} \text{ (Farad)}$$

For voltage setpoint control:

$$PAVCAP = 1.28E - 6 \times \frac{LI}{PAV} \text{ (Farad)}$$

$$ERCAP = \frac{PAVCAP}{2} \text{ (Farad)}$$

where PAV is the average power required and LI (mW/mA) is the typical slope efficiency at 25°C of a batch of lasers that are used in a design. The capacitor value equation is used to get a centered value for the particular type of laser that is used in a design and average power setting. The laser LI can vary by a factor of 7 between different physical lasers of the same type and across temperature without the need to recalculate the PAVCAP and ERCAP values. In ac coupling configuration the LI can be calculated as follows:

$$LI = \frac{P1 - P0}{I_{mod}} \text{ (mW/mA)}$$

where $P1$ is the optical power (mW) at the one level, and $P0$ is the optical power (mW) at the zero level.

These capacitors are placed between the PAVCAP and ERCAP pins and ground. It is important that these capacitors are low leakage multilayer ceramics with an insulation resistance greater than 100 GΩ or a time constant of 1000 sec, whichever is less. The capacitor tolerance may be ±30% from the calculated value to the available off the shelf value including the capacitors own tolerance.

POWER CONSUMPTION

The ADN2870 die temperature must be kept below 125°C. The LFCSP package has an exposed paddle, which should be connected such that it is at the same potential as the ADN2870 ground pins. Power consumption can be calculated as follows:

$$I_{CC} = I_{CC \text{ min}} + 0.3 I_{MOD}$$

$$P = V_{CC} \times I_{CC} + (I_{BIAS} \times V_{BIAS_PIN}) + I_{MOD} (V_{MODP_PIN} + V_{MODN_PIN})/2$$

$$T_{DIE} = T_{AMBIENT} + \theta_{JA} \times P$$

Thus, the maximum combination of $I_{BIAS} + I_{MOD}$ must be calculated.

where:

$I_{CC \text{ min}}$ = 30 mA, the typical value of I_{CC} provided in the Specifications with $I_{BIAS} = I_{MOD} = 0$.

T_{DIE} is the die temperature.

$T_{AMBIENT}$ is the ambient temperature.

V_{BIAS_PIN} is the voltage at the IBIAS pin.

V_{MODP_PIN} is the voltage at the IMODP pin.

V_{MODN_PIN} is the voltage at the IMODN pin.

AUTOMATIC LASER SHUTDOWN (TX_DISABLE)

ALS (TX disable) is an input that is used to shut down the transmitter optical output. The ALS pin is pulled up internally with a 6 kΩ resistor, and conforms to SFP MSA specification. When ALS is logic high or when open, both the bias and modulation currents are turned off.

BIAS AND MODULATION MONITOR CURRENTS

IBMON and IMMON are current-controlled current sources that mirror a ratio of the bias and modulation current. The monitor bias current, IBMON, and the monitor modulation current, IMMON, should both be connected to ground through a resistor to provide a voltage proportional to the bias current and modulation current, respectively. When using a micro-controller, the voltage developed across these resistors can be connected to two of the ADC channels, making available a digital representation of the bias and modulation current.

DATA INPUTS

Data inputs should be ac-coupled (10 nF capacitors are recommended) and are terminated via a 100 Ω internal resistor between the DATAP and DATAN pins. A high impedance circuit sets the common-mode voltage and is designed to allow maximum input voltage headroom over temperature. It is necessary to use ac coupling to eliminate the need for matching between common-mode voltages.

ALARMS

The ADN2870 has a latched active high monitoring alarm (FAIL). The FAIL alarm output is an open drain in conformance to SFP MSA specification requirements.

The ADN2870 has a 3-fold alarm system that covers

- Use of a bias current higher than expected, probably as a result of laser aging.
- Out-of-bounds average voltage at the monitor photodiode (MPD) input, indicating an excessive amount of laser power or a broken loop.

- Undervoltage in IBIAS node (laser diode cathode) that would increase the laser power.

The bias current alarm trip point is set by selecting the value of resistor on the IBMON pin to GND. The alarm is triggered when the voltage on the IBMON pin goes above 1.2 V.

FAIL is activated when the single-point faults in Table 5 occur.

Table 5. ADN2870 Single-Point Alarms

Alarm Type	Pin Name	Over Voltage or Short to VCC Condition	Under Voltage or Short to GND Condition
1. Bias Current	IBMON	Alarm if > 1.2 V	Ignore
2. MPD Current	PAVSET	Alarm if > 1.7 V	Alarm if < 0.9 V
3. Crucial Nodes	ERREF	Alarm if shorted to VCC	Alarm if shorted to GND
	IBIAS	Ignore	Alarm if < 600 mV

Table 6. ADN2870 Response to Various Single-Point Faults in AC-Coupled Configuration as Shown in Figure 32

Pin	Short to VCC	Short to GND	Open
CCBIAS	Fault state occurs	Fault state occurs	Does not increase laser average power
PAVSET	Fault state occurs	Fault state occurs	Fault state occurs
PAVREF	Voltage mode: Fault state occurs Resistor mode: Tied to VCC	Fault state occurs	Fault state occurs
RPAV	Voltage mode: Fault state occurs Resistor mode: Tied to VCC	Fault state occurs	Voltage mode: Fault state occurs Resistor mode: Does not increase average power
ERCAP	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
PAVCAP	Fault state occurs	Fault state occurs	Fault state occurs
DATAP	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
DATAN	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
ALS	Output currents shut off	Normal currents	Output currents shut off
ERSET	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
IMMON	Does not affect laser power	Does not increase laser average power	Does not increase laser average power
ERREF	Voltage mode: Fault state occurs Resistor mode: Tied to VCC	Voltage mode: Does not increase average power Resistor mode: Fault state occurs	Does not increase laser average power
IBMON	Fault state occurs	Does not increase laser average power	Does not increase laser average power
FAIL	Fault state occurs	Does not increase laser average power	Does not increase laser average power
IMODP	Does not increase laser average power	Does not increase laser average power	Does not increase laser average power
IMODN	Does not increase laser average power	Does not increase laser average power	Does not increase laser power
IBIAS	Fault state occurs	Fault state occurs	Fault state occurs
