

OPT301

INTEGRATED PHOTODIODE AND AMPLIFIER

FEATURES

- **PHOTODIODE SIZE:** 0.090 x 0.090 inch (2.29 x 2.29mm)
- **1M Ω FEEDBACK RESISTOR**
- **HIGH RESPONSIVITY:** 0.47A/W (650nm)
- **IMPROVED UV RESPONSE**
- **LOW DARK ERRORS:** 2mV
- **BANDWIDTH:** 4kHz
- **WIDE SUPPLY RANGE:** ± 2.25 to ± 18 V
- **LOW QUIESCENT CURRENT:** 400 μ A
- **HERMETIC TO-99**

APPLICATIONS

- **MEDICAL INSTRUMENTATION**
- **LABORATORY INSTRUMENTATION**
- **POSITION AND PROXIMITY SENSORS**
- **PHOTOGRAPHIC ANALYZERS**
- **SMOKE DETECTORS**

DESCRIPTION

The OPT301 is an opto-electronic integrated circuit containing a photodiode and transimpedance amplifier on a single dielectrically isolated chip. The transimpedance amplifier consists of a precision FET-input op amp and an on-chip metal film resistor. The 0.09 x 0.09 inch photodiode is operated at zero bias for excellent linearity and low dark current.

The integrated combination of photodiode and transimpedance amplifier on a single chip eliminates the problems commonly encountered in discrete designs such as leakage current errors, noise pick-up and gain peaking due to stray capacitance.

The OPT301 operates over a wide supply range (± 2.25 to ± 18 V) and supply current is only 400 μ A. It is packaged in a hermetic TO-99 metal package with a glass window, and is specified for the -40°C to 85°C temperature range.

PIN CONFIGURATION

ABSOLUTE MAXIMUM RATINGS

Supply Voltage	$\pm 18V$
Input Voltage Range (Common Pin)	$\pm V_S$
Output Short-Circuit (to ground)	Continuous
Operating Temperature	$-55^{\circ}C$ to $+125^{\circ}C$
Storage Temperature	$-55^{\circ}C$ to $+125^{\circ}C$
Junction Temperature	$+125^{\circ}C$
Lead Temperature (soldering, 10s)	$+300^{\circ}C$

ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Burr-Brown recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

APPLICATIONS INFORMATION

Figure 1 shows the basic connections required to operate the OPT301. Applications with high-impedance power supplies may require decoupling capacitors located close to the device pins as shown. Output is zero volts with no light and increases with increasing illumination.

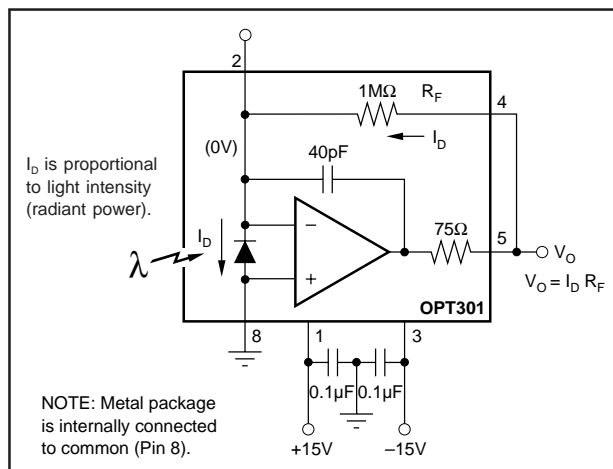

FIGURE 1. Basic Circuit Connections.

Photodiode current, I_D , is proportional to the radiant power or flux (in watts) falling on the photodiode. At a wavelength of 650nm (visible red) the photodiode Responsivity, R_P , is approximately 0.45A/W. Responsivity at other wavelengths is shown in the typical performance curve “Responsivity vs Wavelength.”

The typical performance curve “Output Voltage vs Radiant Power” shows the response throughout a wide range of radiant power. The response curve “Output Voltage vs Irradiance” is based on the photodiode area of $5.23 \times 10^{-6} \text{m}^2$.

The OPT301’s voltage output is the product of the photodiode current times the feedback resistor, ($I_D R_F$). The internal feedback resistor is laser trimmed to $1\text{M}\Omega \pm 2\%$. Using this resistor, the output voltage responsivity, R_V , is approximately $0.45\text{V}/\mu\text{W}$ at 650nm wavelength.

An external resistor can be used to set a different voltage responsivity. For values of R_F less than $1\text{M}\Omega$, an external capacitor, C_{EXT} , should be connected in parallel with R_F (see Figure 2). This capacitor eliminates gain peaking and prevents instability. The value of C_{EXT} can be read from the table in Figure 2.

LIGHT SOURCE POSITIONING

The OPT301 is 100% tested with a light source that uniformly illuminates the full area of the integrated circuit, including the op amp. Although all IC amplifiers are light-sensitive to some degree, the OPT301 op amp circuitry is designed to minimize this effect. Sensitive junctions are shielded with metal, and differential stages are cross-coupled. Furthermore, the photodiode area is very large relative to the op amp input circuitry making these effects negligible.

If your light source is focused to a small area, be sure that it is properly aimed to fall on the photodiode. If a narrowly focused light source were to miss the photodiode area and fall only on the op amp circuitry, the OPT301 would not perform properly. The large (0.090×0.090 inch) photodiode area allows easy positioning of narrowly focused light sources. The photodiode area is easily visible—it appears very dark compared to the surrounding active circuitry.

The incident angle of the light source also affects the apparent sensitivity in uniform irradiance. For small incident angles, the loss in sensitivity is simply due to the smaller effective light gathering area of the photodiode (proportional to the cosine of the angle). At a greater incident angle, light is reflected and scattered by the side of the package. These effects are shown in the typical performance curve “Response vs Incident Angle.”

DARK ERRORS

The dark errors in the specification table include all sources. The dominant error source is the input offset voltage of the op amp. Photodiode dark current and input bias current of the op amp are approximately 2pA and contribute virtually no offset error at room temperature. Dark current and input bias current double for each 10°C above 25°C . At 70°C , the error current can be approximately 100pA. This would produce a 1mV offset with $R_F = 10\text{M}\Omega$. The OPT301 is useful with feedback resistors of $100\text{M}\Omega$ or greater at room temperature. The dark output voltage can be trimmed to zero with the optional circuit shown in Figure 3.

6

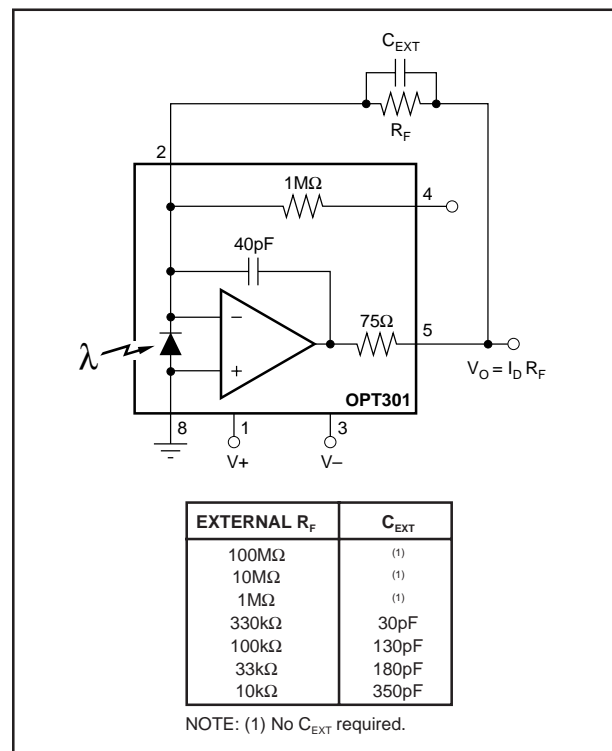

FIGURE 2. Using External Feedback Resistor.

When used with very large feedback resistors, tiny leakage currents on the circuit board can degrade the performance of the OPT301. Careful circuit board design and clean assembly procedures will help achieve best performance. A “guard trace” on the circuit board can help minimize leakage to the critical non-inverting input (pin 2). This guard ring should encircle pin 2 and connect to Common, pin 8.

DYNAMIC RESPONSE

Using the internal $1\text{M}\Omega$ resistor, the dynamic response of the photodiode/op amp combination can be modeled as a simple R/C circuit with a -3dB cutoff frequency of 4kHz . This yields a rise time of approximately $90\mu\text{s}$ (10% to 90%). Dynamic response is not limited by op amp slew rate. This is demonstrated by the dynamic response oscilloscope photographs showing virtually identical large-signal and small-signal response.

Dynamic response will vary with feedback resistor value as shown in the typical performance curve “Voltage Output Responsivity vs Frequency.” Rise time (10% to 90%) will vary according to the -3dB bandwidth produced by a given feedback resistor value—

$$t_R \approx \frac{0.35}{f_C} \quad (1)$$

where:

t_R is the rise time (10% to 90%)

f_C is the -3dB bandwidth

LINEARITY PERFORMANCE

Current output of the photodiode is very linear with radiant power throughout a wide range. Nonlinearity remains below

approximately 0.02% up to $100\mu\text{A}$ photodiode current. The photodiode can produce output currents of 1mA or greater with high radiant power, but nonlinearity increases to several percent in this region.

This excellent linearity at high radiant power assumes that the full photodiode area is uniformly illuminated. If the light source is focused to a small area of the photodiode, nonlinearity will occur at lower radiant power.

NOISE PERFORMANCE

Noise performance of the OPT301 is determined by the op amp characteristics in conjunction with the feedback components and photodiode capacitance. The typical performance curve “Output Noise Voltage vs Measurement Bandwidth” shows how the noise varies with R_F and measured bandwidth (1Hz to the indicated frequency). The signal bandwidth of the OPT301 is indicated on the curves. Noise can be reduced by filtering the output with a cutoff frequency equal to the signal bandwidth.

Output noise increases in proportion to the square-root of the feedback resistance, while responsivity increases linearly with feedback resistance. So best signal-to-noise ratio is achieved with large feedback resistance. This comes with the trade-off of decreased bandwidth.

The noise performance of a photodetector is sometimes characterized by Noise Effective Power (NEP). This is the radiant power which would produce an output signal equal to the noise level. NEP has the units of radiant power (watts). The typical performance curve “Noise Effective Power vs Measurement Bandwidth” shows how NEP varies with R_F and measurement bandwidth.
