CY62126BV

64K x 16 Static RAM

Features

- **2.7V–3.6V operation**
- **CMOS for optimum speed/power**
- **Low active power (70 ns, LL version)**
  - **— 54 mW (max.) (15 mA)**
- **Low standby power (70 ns, LL version)**
  - **— 54 μW (max.) (15 μA)**
- **Automatic power-down when deselected**
- **Independent control of Upper and Lower Bytes**
- **Available in 44-pin TSOP II (forward) and fBGA**

Functional Description

The CY62126BV is a high-performance CMOS static RAM organized as 65,536 words by 16 bits. This device has an automatic power-down feature that significantly reduces power consumption by 99% when deselected. The device enters power-down mode when $\overline{CE}$ is HIGH.
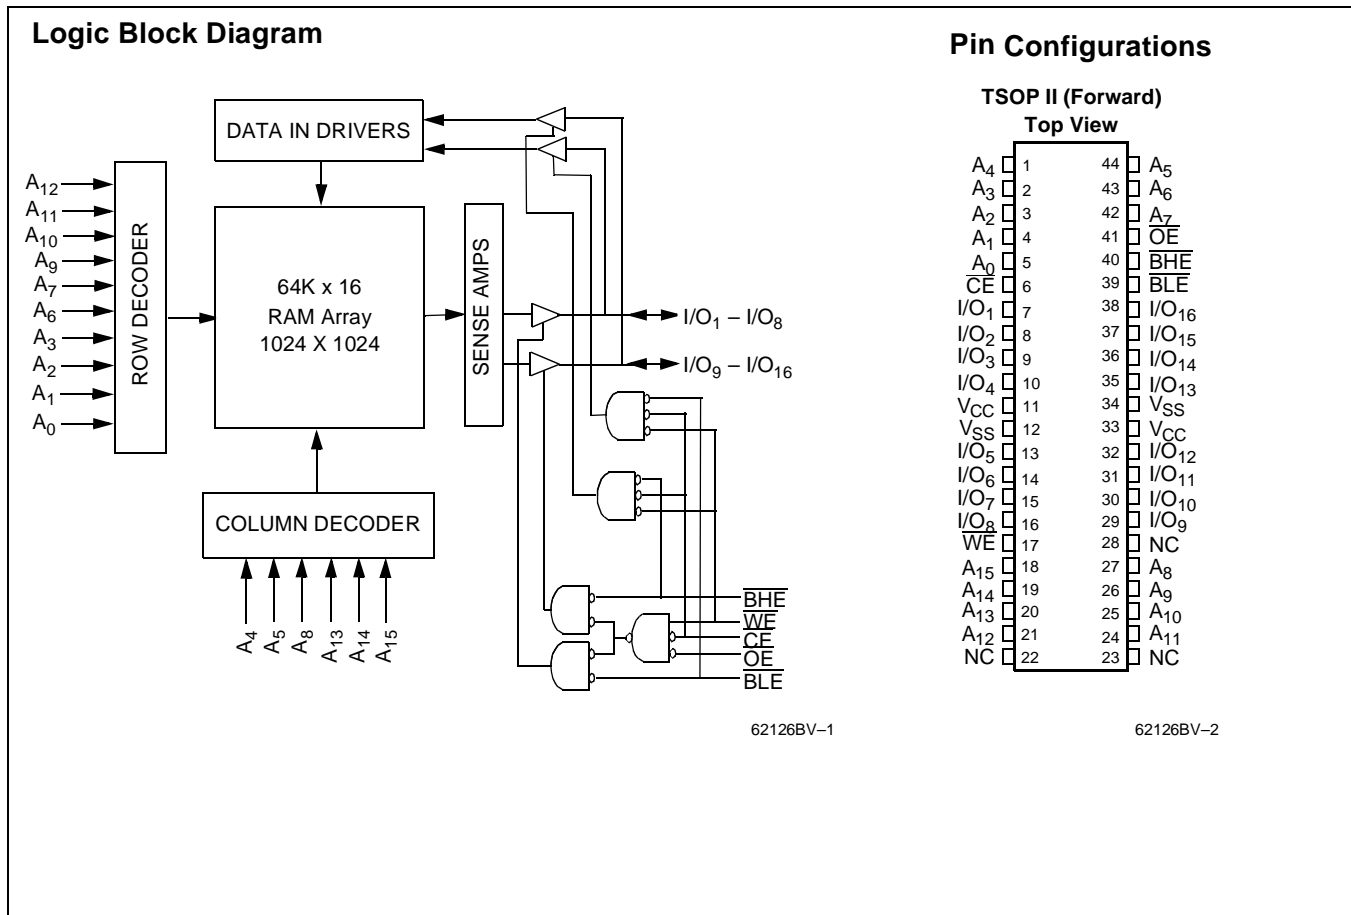

Writing to the device is accomplished by taking Chip Enable ($\overline{CE}$) and Write Enable ($\overline{WE}$) inputs LOW. If Byte Low Enable ($\overline{BLE}$) is LOW, then data from I/O pins (I/O$_1$ through I/O$_8$), is written into the location specified on the address pins (A_0 through A_{15}). If Byte High Enable ($\overline{BHE}$) is LOW, then data from I/O pins (I/O$_9$ through I/O$_{16}$) is written into the location specified on the address pins (A_0 through A_{15}).

Reading from the device is accomplished by taking Chip Enable ($\overline{CE}$) and Output Enable ($\overline{OE}$) LOW while forcing the write enable ($\overline{WE}$) HIGH. If Byte Low Enable ($\overline{BLE}$) is LOW, then data from the memory location specified by the address pins will appear on I/O$_1$ to I/O$_8$. If Byte High Enable ($\overline{BHE}$) is LOW, then data from memory will appear on I/O$_9$ to I/O$_{16}$. See the truth table at the back of this data sheet for a complete description of read and write modes.

The input/output pins (I/O$_1$ through I/O$_{16}$) are placed in a high-impedance state when the device is deselected ($\overline{CE}$ HIGH), the outputs are disabled ($\overline{OE}$ HIGH), the $\overline{BHE}$ and $\overline{BLE}$ are disabled ($\overline{BHE}$, $\overline{BLE}$ HIGH), or during a write operation ($\overline{CE}$ LOW, and $\overline{WE}$ LOW).

The CY62126BV is available in standard 44-pin TSOP Type II (forward pinout) and fBGA packages.

Notes:
3. Typical specifications are the mean values measured over a large sample size across normal production process variations and are taken at nominal conditions (T_A = 25°C, V_{CC}=3.0V). Parameters are guaranteed by design and characterization, and not 100% tested.
4. Tested initially and after any design or process changes that may affect these parameters.

Notes:
5. Test conditions assume signal transition time of 5 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance.
6. t_{HZOE}, t_{HZCE}, t_{HZWE}, and t_{HZBE} are specified with a load capacitance of 5 pF as in part (b) of AC Test Loads. Transition is measured ±500 mV from steady-state voltage.
7. At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE}, t_{HZOE} is less than t_{LZOE}, t_{HZWE} is less than t_{LZWE}, and t_{HZBE} is less than t_{LZBE}, for any given device.
8. The internal write time of the memory is defined by the overlap of $\overline{CE}$ LOW and $\overline{WE}$ LOW. $\overline{CE}$ and $\overline{WE}$ must be LOW to initiate a write, and the transition of any of these signals can terminate the write. The input data set-up and hold timing should be referenced to the leading edge of the signal that terminates the write. Refer to truth table for further conditions from $\overline{BHE}$ and $\overline{BLE}$.
