

500MHz Rail-to-Rail Amplifiers

The EL8202, EL8203, and EL8403 represent rail-to-rail amplifiers with a -3dB bandwidth of 500MHz and slew

rate of 600V/μs. Running off a very low supply current of 5.6mA per channel, the EL8202, EL8203, and EL8403 also feature inputs that go to 0.15V below the V_{S-} rail. The EL8202 and EL8203 are dual channel amplifiers. The EL8403 is a quad channel amplifier.

The EL8202 includes a fast-acting disable/power-down circuit. With a 25ns disable and a 200ns enable, the EL8202 is ideal for multiplexing applications.

The EL8202, EL8203, and EL8403 are designed for a number of general purpose video, communication, instrumentation, and industrial applications. The EL8202 is available in a 10-pin MSOP package, the EL8203 in an 8-pin SO package, and the EL8403 in 14-pin SO and 16-pin QSOP packages. All are specified for operation over the -40°C to +85°C temperature range.

Features

- 500MHz -3dB bandwidth
- 600V/μs slew rate
- Low supply current = 5.6mA per channel
- Supplies from 3V to 5.5V
- Rail-to-rail output
- Input to 0.15V below V_{S-}
- Fast 25ns disable (EL8202 only)
- Low cost

Applications

- Video amplifiers
- Portable/hand-held products
- Communications devices

Simplified Schematic Diagram

Description of Operation and Application Information

Product Description

The EL8202, EL8203 and EL8403 are wide bandwidth, single supply, low power and rail-to-rail output voltage feedback operational amplifiers. The amplifiers are internally compensated for closed loop gain of +1 or greater. Connected in voltage follower mode and driving a 1kΩ load, the EL8202, EL8203 and EL8403 have a -3dB bandwidth of 500MHz. Driving a 150Ω load, the bandwidth is about 350MHz while maintaining a 600V/μs slew rate. The EL8202 is available with a power down pin to reduce power to 30μA typically while the amplifier is disabled.

Input, Output and Supply Voltage Range

The EL8202, EL8203 and EL8403 have been designed to operate with a single supply voltage from 3V to 5.0V. Split supplies can also be used as long as their total voltage is within 3V to 5.0V. The amplifiers have an input common mode voltage range from 0.15V below the negative supply (VS- pin) to within 1.5V of the positive supply (VS+ pin). If the input signal is outside the above specified range, it will cause the output signal to be distorted.

The output of the EL8202, EL8203 and EL8403 can swing rail to rail. As the load resistance becomes lower, the ability to drive close to each rail is reduced. For the load resistor 1kΩ, the output swing is about 4.9V at a 5V supply. For the load resistor 150Ω, the output swing is about 4.6V.

Choice of Feedback Resistor and Gain Bandwidth Product

For applications that require a gain of +1, no feedback resistor is required. Just short the output pin to the inverting input pin. For gains greater than +1, the feedback resistor forms a pole with the parasitic capacitance at the inverting input. As this pole becomes smaller, the amplifier's phase margin is reduced. This causes ringing in the time domain and peaking in the frequency domain. Therefore, R_F has some maximum value that should not be exceeded for optimum performance. If a large value of R_F must be used, a small capacitor in the few pF range in parallel with R_F can help to reduce the ringing and peaking at the expense of reducing the bandwidth.

As far as the output stage of the amplifier is concerned, the output stage is also a gain stage with the load. R_F and R_G appear in parallel with R_L for gains other than +1. As this combination gets smaller, the bandwidth falls off. Consequently, R_F also has a minimum value that should not be exceeded for optimum performance. For gain of +1, $R_F=0$ is optimum. For the gains other than +1, optimum response is obtained with R_F between 300 Ω to 1k Ω .

The EL8202, EL8203 and EL8403 have a gain bandwidth product of 200MHz. For gains ≥ 5 , its bandwidth can be predicted by the following equation:

$$\text{Gain} \times \text{BW} = 200\text{MHz}$$

Video Performance

For good video performance, an amplifier is required to maintain the same output impedance and the same frequency response as DC levels are changed at the output. This is especially difficult when driving a standard video load of 150 Ω , because the change in output current with DC level. Special circuitry has been incorporated in the EL8202, EL8203 and EL8403 to reduce the variation of the output impedance with the current output. This results in dG and dP specifications of 0.01% and 0.01°, while driving 150 Ω at a gain of 2. Driving high impedance loads would give a similar or better dG and dP performance.

Driving Capacitive Loads and Cables

The EL8202, EL8203 and EL8403 can drive 5pF loads in parallel with 1k Ω with less than 5dB of peaking at gain of +1. If less peaking is desired in applications, a small series resistor (usually between 5 Ω to 50 Ω) can be placed in series with the output to eliminate most peaking. However, this will reduce the gain slightly. If the gain setting is greater than 1, the gain resistor R_G can then be chosen to make up for any gain loss which may be created by the additional series resistor at the output.

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, a back-termination series resistor at the amplifier's output will isolate the amplifier from the cable and

allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. Again, a small series resistor at the output can help to reduce peaking.

Disable/Power-Down

The EL8202 can be disabled and placed its output in a high impedance state. The turn off time is about 25ns and the turn on time is about 200ns. When disabled, the amplifier's supply current is reduced to 40 μ A typically, thereby effectively eliminating the power consumption. The amplifier's power down can be controlled by standard TTL or CMOS signal levels at the ENABLE pin. The applied logic signal is relative to V_{S-} pin. Letting the ENABLE pin float or applying a signal that is less than 0.8V above V_{S-} will enable the amplifier. The amplifier will be disabled when the signal at ENABLE pin is 2V above V_{S-} .

Output Drive Capability

The EL8202, EL8203 and EL8403 do not have internal short circuit protection circuitry. They have a typical short circuit current of 80mA sourcing and 150mA sinking for the output is connected to half way between the rails with a 10 Ω resistor. If the output is shorted indefinitely, the power dissipation could easily increase such that the part will be destroyed. Maximum reliability is maintained if the output current never exceeds ± 40 mA. This limit is set by the design of the internal metal interconnections.

Power Dissipation

With the high output drive capability of the EL8202, EL8203 and EL8403. It is possible to exceed the 125°C absolute maximum junction temperature under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if the load conditions or package types need to be modified for the amplifier to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to:

$$PD_{MAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}}$$

Where:

T_{JMAX} = Maximum junction temperature

T_{AMAX} = Maximum ambient temperature

θ_{JA} = Thermal resistance of the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or:

For sourcing:

$$PD_{MAX} = V_S \times I_{SMAX} + \Sigma(V_S - V_{OUTi}) \times \frac{V_{OUTi}}{R_{Li}}$$

For sinking:

$$PD_{MAX} = V_S \times I_{SMAX} + \Sigma(V_{OUTi} - V_S) \times I_{LOADi}$$

Where:

V_S = Total supply voltage

I_{SMAX} = Maximum quiescent supply current

V_{OUTi} = Maximum output voltage of the application for each channel

R_{LOADi} = Load resistance tied to ground for each channel

I_{LOADi} = Load current for each channel

By setting the two PD_{MAX} equations equal to each other, we can solve the output current and R_{LOADi} to avoid the device overheat.

Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, a good printed circuit board layout is necessary for optimum performance. Lead lengths should be as short as possible. The power supply pin must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the V_{S-} pin is connected to the ground plane, a single 4.7µF tantalum capacitor in parallel with a 0.1µF ceramic capacitor from V_{S+} to GND will suffice. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used. In this case, the V_{S-} pin becomes the negative supply rail.

For good AC performance, parasitic capacitance should be kept to a minimum. Use of wire wound resistors should be avoided because of their additional series inductance. Use of sockets should also be avoided if possible. Sockets add parasitic inductance and capacitance that can result in compromised performance. Minimizing parasitic capacitance at the amplifier's inverting input pin is very important. The feedback resistor should be placed very close to the inverting input pin. Strip line design techniques are recommended for the signal traces.

Typical Applications

VIDEO SYNC PULSE REMOVER

Many CMOS analog to digital converters have a parasitic latch up problem when subjected to negative input voltage levels. Since the sync tip contains no useful video information and it is a negative going pulse, we can chop it off. Figure 32 shows a gain of 2 connections. Figure 33 shows the complete input video signal applied at the input,

as well as the output signal with the negative going sync pulse removed.

FIGURE 32. SYNC PULSE REMOVER

FIGURE 33. VIDEO SIGNAL

MULTIPLEXER

Besides the normal power down usage, the \overline{ENABLE} pin of the EL8202 can be used for multiplexing applications. Figure 34 shows two EL8202 with the outputs tied together, driving a back terminated 75Ω video load. A 2V_{P-P} 2MHz sine wave is applied to Amp A and a 1V_{P-P} 2MHz sine wave is applied to Amp B. Figure 33 shows the \overline{ENABLE} signal and the resulting output waveform at V_{OUT} . Observe the break-before-make operation of the multiplexing. Amp A is on and V_{IN1} is passed through to the output when the \overline{ENABLE} signal is low and turns off in about 25ns when the \overline{ENABLE} signal is high. About 200ns later, Amp B turns on and V_{IN2} is passed through to the output. The break-before-make operation ensures that more than one amplifier isn't trying to drive the bus at the same time.

FIGURE 34. TWO TO ONE MULTIPLEXER

FIGURE 35.

SINGLE SUPPLY VIDEO LINE DRIVER

The EL8202, EL8203 and EL8403 are wideband rail-to-rail output op amplifiers with large output current, excellent dG, dP, and low distortion that allow them to drive video signals in low supply applications. Figure 36 is the single supply non-inverting video line driver configuration and Figure 37 is the inverting video line driver configuration. The signal is AC coupled by C_1 . R_1 and R_2 are used to level shift the input and output to provide the largest output swing. R_F and R_G set the AC gain. C_2 isolates the virtual ground potential. R_T and R_3 are the termination resistors for the line. C_1 , C_2 and C_3 are selected big enough to minimize the droop of the luminance signal.
