## 3V, Ultra-Low-Power Quadrature Modulator/Demodulator

### General Description

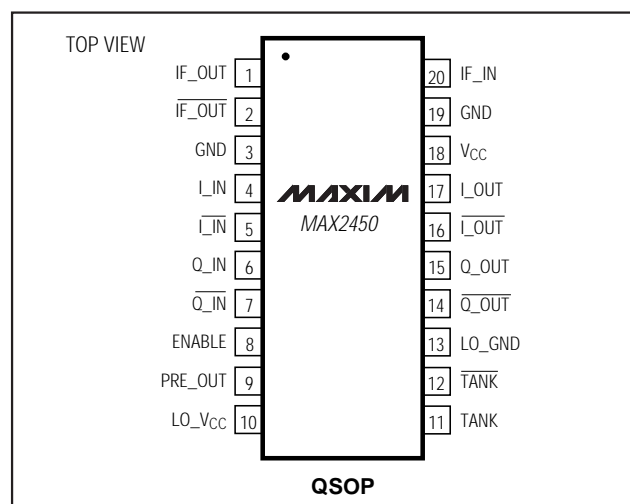

The MAX2450 combines a quadrature modulator and quadrature demodulator with a supporting oscillator and divide-by-8 prescaler on a monolithic IC. It operates from a single +3V supply and draws only 5.9mA. The demodulator accepts an amplified and filtered IF signal in the 35MHz to 80MHz range, and demodulates it into I and Q baseband signals with 51dB of voltage conversion gain. The IF input is terminated with a 400Ω thin-film resistor for matching to an external IF filter. The baseband outputs are fully differential and have 1.2Vp-p signal swings. The modulator accepts differential I and Q baseband signals with amplitudes up to 1.35Vp-p and bandwidths to 15MHz, and produces a differential IF signal in the 35MHz to 80MHz range.

Pulling the CMOS-compatible ENABLE pin low shuts down the MAX2450 and reduces the supply current to less than 1μA. To minimize spurious feedback, the MAX2450's internal oscillator is set at twice the IF via external tuning components. The oscillator and associated phase shifters produce differential signals exhibiting low amplitude and phase imbalance, yielding modulator sideband rejection of 38dB. The MAX2450 comes in a QSOP package.

### Applications

Digital Cordless Phones  
GSM and North American Cellular Phones  
Wireless LANs  
Digital Communications  
Two-Way Pagers

### Pin Configuration

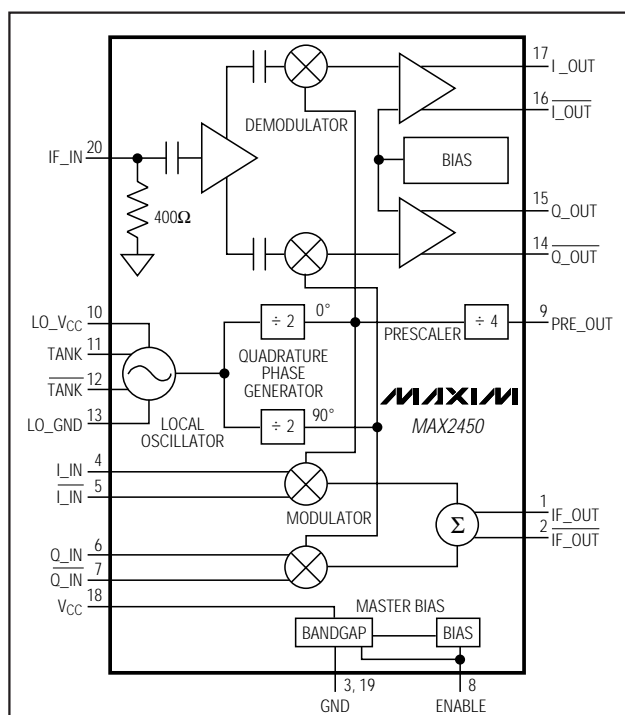

### Features

- ◆ Combines Quadrature Modulator and Demodulator
- ◆ Integrated Quadrature Phase Shifters
- ◆ On-Chip Oscillator (Requires External Tuning Circuit)
- ◆ On-Chip Divide-by-8 Prescaler
- ◆ Modulator Input Bandwidth Up to 15MHz
- ◆ Demodulator Output Bandwidth Up to 9MHz
- ◆ 51dB Demodulator Voltage Conversion Gain
- ◆ CMOS-Compatible Enable
- ◆ 5.9mA Operating Supply Current  
1μA Shutdown Supply Current

### Ordering Information

PART	TEMP. RANGE	PIN-PACKAGE
MAX2450CEP	0°C to +70°C	20 QSOP

# 3V, Ultra-Low-Power Quadrature Modulator/Demodulator

## ABSOLUTE MAXIMUM RATINGS

V<sub>CC</sub>, LO\_V<sub>CC</sub> to GND ..... -0.3V to +4.5V  
 ENABLE, TANK,  $\overline{\text{TANK}}$ , I<sub>IN</sub>,  $\overline{\text{I}}_{\text{IN}}$ , Q<sub>IN</sub>,  
 $\overline{\text{Q}}_{\text{IN}}$  to GND ..... -0.3V to (V<sub>CC</sub> + 0.3V)  
 IF\_IN to GND ..... -0.3V to +1.5V

Continuous Power Dissipation (T<sub>A</sub> = +70°C)  
 QSOP (derate 9.1mW/°C above +70°C) ..... 727mW  
 Operating Temperature Range ..... 0°C to +70°C  
 Storage Temperature Range ..... -65°C to +165°C  
 Lead Temperature (soldering, 10sec) ..... +300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## DC ELECTRICAL CHARACTERISTICS

(V<sub>CC</sub> = LO\_V<sub>CC</sub> = TANK = 2.7V to 3.3V, ENABLE = V<sub>CC</sub> - 0.4, GND = LO\_GND = 0V, I<sub>IN</sub> =  $\overline{\text{I}}_{\text{IN}}$  = Q<sub>IN</sub> =  $\overline{\text{Q}}_{\text{IN}}$  = IF\_IN = TANK = OPEN, T<sub>A</sub> = 0°C to +70°C, unless otherwise noted.)

## Detailed Description

The following sections describe each of the functional blocks shown in the *Functional Diagram*. They also refer to the Typical Application Block Diagram (Figure 1).

### Demodulator

The demodulator contains a single-ended-to-differential converter, two Gilbert-cell multipliers, and two fixed gain stages. The IF signal should be AC coupled into IF\_IN. Internally, IF\_IN is terminated with a 400 $\Omega$  resistor to GND and provides a gain of 14dB. This amplified IF signal is fed into the I and Q mixers for demodulation. The multipliers mix the IF signal with the quadrature LO signals, resulting in baseband I and Q signals. The conversion gain of the multipliers is 15dB. These signals are further amplified by 21dB by the baseband amplifiers. The baseband I and Q amplifier chains are DC coupled.

### Local Oscillator

The local-oscillator section is formed by an emitter-coupled differential pair. Figure 2 shows the equivalent local-oscillator circuit schematic. An external LC resonant tank determines the oscillation frequency, and the Q of this resonant tank affects the oscillator phase noise. The oscillation frequency is twice the IF frequency, so that the quadrature phase generator can use two latches to generate precise quadrature signals.

The oscillator may be overdriven by an external source. The source should be AC coupled into TANK/TANK-bar,

and should provide 200mVp-p levels. A choke (typically 2.2 $\mu$ H) is required between TANK and TANK-bar. Differential input impedance at TANK/TANK-bar is 10k $\Omega$ . For single-ended drive, connect an AC bypass capacitor (1000pF) from TANK to GND, and AC couple TANK to the source.

### Quadrature Phase Generator

The quadrature phase generator uses two latches to divide the local-oscillator frequency by two, and generates two precise quadrature signals. Internal limiting amplifiers shape the signals to approximate square waves to drive the Gilbert-cell mixers. The inphase signal (at half the local-oscillator frequency) is further divided by four for the prescaler output.

### Prescaler

The prescaler output, PRE\_OUT, is buffered and swings typically 0.35Vp-p with a 10k $\Omega$  and 6pF load. It can be AC-coupled to the input of a frequency synthesizer.

### Modulator

The modulator accepts I and Q differential baseband signals up to 1.35Vp-p with frequencies up to 15MHz, and upconverts them to the IF frequency. Since these inputs are biased internally at around 1.5V, I and Q signals should be capacitively coupled into these high-impedance ports (the differential input impedance is approximately 44k $\Omega$ ). The self-bias design yields very low on-chip offset, resulting in excellent carrier sup-

## 3V, Ultra-Low-Power Quadrature Modulator/Demodulator

pression. Alternatively, a differential DAC may be connected without AC coupling, as long as a common-mode voltage range of 1.25V to 1.75V is maintained. For single-ended drive, connect  $\overline{I\_IN}$  and  $\overline{Q\_IN}$  via AC-coupling capacitors (0.1 $\mu$ F) to GND.

The IF output is designed to drive a high impedance (> 20k $\Omega$ ), such as an IF buffer or an upconverter mixer.  $\overline{IF\_OUT}/IF\_OUT$  must be AC coupled to the load. Impedances as low as 200 $\Omega$  can be driven with a decrease in output amplitude (Figure 3). To drive a single-ended load, AC couple and terminate  $\overline{IF\_OUT}$  with a resistive load equal to the load at IF\_OUT.

### Master Bias

During normal operation, ENABLE should remain above  $V_{CC} - 0.4V$ . Pulling the ENABLE input low shuts off the master bias and reduces the circuit current to less than 2 $\mu$ A. The master bias section includes a bandgap reference generator and a PTAT (Proportional To Absolute Temperature) current generator.

### Applications Information

Figure 4 shows the implementation of a resonant tank circuit. The inductor, two capacitors, and a dual varactor form the oscillator's resonant circuit. In Figure 4, the oscillator frequency ranges from 130MHz to 160MHz.

To ensure reliable start-up, the inductor is directly connected across the local oscillator's tank ports. The two 33pF capacitors affect the Q of the resonant circuit. Other values may be chosen to meet individual application requirements. Use the following formula to determine the oscillation frequency:

$$f_o = \frac{1}{2\pi\sqrt{L_{EQ}C_{EQ}}}$$

where

$$C_{EQ} = \frac{1}{\frac{1}{C_1} + \frac{1}{C_2} + \frac{2}{C_{VAR}}} + C_{STRAY}$$

and

$$L_{EQ} = L + L_{STRAY}$$

where  $C_{STRAY}$  = parasitic capacitance and  $L_{STRAY}$  = parasitic inductance.

To alter the oscillation frequency range, change the inductance, the capacitance, or both. For best phase-noise performance keep the Q of the resonant tank as high as possible:

$$Q = R_{EQ} \sqrt{\frac{C_{EQ}}{L_{EQ}}}$$

where  $R_{EQ} \approx 10k\Omega$  (Figure 2).

The oscillation frequency can be changed by altering the control voltage,  $V_{CTRL}$ .

Figure 4. Typical Resonant Tank Circuit
