DESCRIPTION

The 74ALVC162836A is an 20-bit universal bus driver. Data flow is controlled by output enable (\overline{OE}), latch enable (\overline{LE}) and clock inputs (CP).

When \overline{LE} is HIGH, the A to Y data flow is transparent. When \overline{LE} is HIGH and CP is held at LOW or HIGH, the data is latched; on the LOW to HIGH transient of CP the A-data is stored in the latch/flip-flop.

The 74ALVC162836A is designed with 30 Ω series resistors in both HIGH or LOW output stages.

When \overline{OE} is LOW the outputs are active. When \overline{OE} is HIGH, the outputs go to the high impedance OFF-state. Operation of the \overline{OE} input does not affect the state of the latch/flip-flop.

To ensure the high-impedance state during power up or power down, \overline{OE} should be tied to V_{CC} through a pullup resistor; the minimum value of the resistor is determined by the current-sinking capability of the driver.

NOTES:

1. C_{PD} is used to determine the dynamic power dissipation (P_D in μW):
 $P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o)$ where: f_i = input frequency in MHz; C_L = output load capacitance in pF;
 f_o = output frequency in MHz; V_{CC} = supply voltage in V; $\sum (C_L \times V_{CC}^2 \times f_o)$ = sum of outputs.
