FM/IF system and microcomputer-based tuning interface

TEA6100

GENERAL DESCRIPTION

The TEA6100 is a FM/IF system circuit intended for microcomputer controlled radio receivers. The circuit includes highly sensitive analogue circuitry. The digital circuitry, including an I²C bus, controls the analogue circuitry and the AM/FM tuning and stop information for the microcomputer.

Features

- 4-stage symmetrical IF limiting amplifier
- Software selectable AM or FM input
- Symmetrical quadrature demodulator
- Single-ended LF output stage
- D.C. output level determined by the input signal
- Semi-adjustable AM and FM level voltage
- Multi-path detector/rectifier/amplifier circuitry
- 3-bit level information and 3-bit multi-path information
- Signal dependent 'soft' muting circuit; externally adjustable
- Reference voltage output (FM mode only)
- 8-bit AM/FM frequency counter with selectable counter resolution
- Possibility to measure the AM IF frequency at 460 kHz (250 Hz resolution) and 10,7 MHz (500 Hz resolution)
- Reference frequency can be directly connected to the reference frequency output of a frequency synthesizer (TSA6057, 40 kHz) .

PACKAGE OUTLINE

20-lead DIL; plastic (SOT146); SOT146-1; 1996 August 13.

FUNCTIONAL DESCRIPTION (see Figs 1 and 16)

The IF amplifier consists of four balanced limiting amplifier stages, two separate inputs (AM and FM) and one output. Software programming (see Table 2; Figs 4 and 5) allows the input signals (AM/FM) to be inserted on either input (pin 18 or 19). The output drives the frequency counter and via the mute stage, drives the quadrature detector. The output of the quadrature detector is applied to an audio stage (which has a single-ended output). The AM/FM level amplifier, which is driven by 5 IF level detectors, generates a signal dependent d.c. voltage. The level output voltage is used internally to control the mute stage and, if required, the signal can be used externally to control the stereo channel separation and frequency response of a stereo decoder. The signal is also feed to the analogue-to-digital converter (ADC). Due to the front-end spread in the amplification, the level voltage is made adjustable (LADJ, pin 14). The level voltage amplifier controls the mute stage and this insures the -3 dB limiting point remains constant, independent of the front-end spread. AM and FM mode have different front-end circuitry, therefore LADJ must be adjustable for both inputs.

The output voltage of the level amplifier is dependent upon the field strength of the input signal. The multi-path of the FM signal exists in the AM modulation of the input signal. The following method is used to determine the level information and the amount of multi-path (as a DC voltage):

- the IF level detector detects the multi-path and feds the signal, via the level amplifiers, to the external bandpass filter (pin 3) and ADC1
- the signal is then fed to an internal rectifier
- the rectified signal is then fed to an amplifier, so at pin 5 the DC level information is externally available and internally used by ADC2

In the FM mode, the DC information concerning the multi-path is available at pin 5 and the level information is available at pin 3.

FM/IF system and microcomputer-based tuning interface

TEA6100

In the AM mode, the level information at pin 3 cannot be directly used owing to AM modulation on the output signal of the level amplifier. This signal requires filtering, which is achieved by the following method:

- the multiplexer is switched to a position which causes the signal to be applied to the attenuator
- after attenuation the signal is fed to an amplifier (the resultant gain of attenuator and amplifier is unity), after amplification the signal is filtered by an internal resistor and external capacitor
- after filtering the signal is applied to ADC2 and is externally available

In AM mode pin 5 contains the level information.

The voltages on pin 3 and 5 are converted into two 3-bit digital words by the ADC, which can then be read out by the I²C bus. The meaning of the 3-bit words is shown in Table 1.

Table 1 3-bit words

WORD	POSITION	
	FM	AM
1	multipath	level without modulation
2	level	level with modulation

The FM modulated signal is converted into an audio signal by the symmetrical quadrature detector. The main advantage of such a detector is that it requires few external components.

An FM signal requires good AM suppression, and as a result, the IF amplifiers must act as limiters. To achieve good suppression on small input signals the IF amplifiers must have a high gain and thus a high sensitivity. High sensitivity is an undesirable property when used in car radio applications, this problem is solved by having an externally adjustable mute stage to control the overall sensitivity of the device.

The IF mute stage is controlled by the level amplifier (soft muting) and is only active in FM mode. If the input falls below a predetermined level, the mute stage becomes active. To avoid the 'ON/OFF' effect of the audio signal due to fluctuations of the input signal, the mute stage is activated rapidly but de-activated slowly. The mute stage is de-activated slowly, via a current source and an external capacitor at pin 2, to avoid aggressive behaviour of the audio signal. It is possible to adjust the '-3 dB limiting point' of the audio output via the level voltage due to the level signal being externally adjustable. If hard muting is required then pin 2 must be switched to ground.

The 8-bit counter allows accurate stop information to be obtained, because exact tuning is achieved when the measured frequency is equal to the centre frequency of the IF filter.

To measure the input frequency, the number of pulses which occur in a defined time must be counted. This defined time is referred to as 'window'. A wide window indicates a long measuring time and therefore a high accuracy. The counter resolution is defined as Hertz per count. Due to the TEA6100 having to measure the IF frequencies of AM and FM, the counter resolution must be adjustable (different channel spacing). The counter resolution depends on the setting of dividers 1 (N1), divider 2 (N2) and the reference frequency (F_{ref}). The divider ratios of N1 and N2 are controlled by software (see section PROGRAMMING INFORMATION). In Table 3 the window and counter resolution has been calculated for a reference frequency of 40 kHz. The accuracy is controlled by bit 7 of the input word. Although the resolution is the same for bit 7 = logic 0 and bit 7 = logic 1, the width of the window doubles when bit 7 = logic 1.

- bit 7 = 0, accuracy = \pm counter resolution
- bit 7 = 1, accuracy = $\pm \frac{1}{2}$ counter resolution

FM/IF system and microcomputer-based tuning interface

TEA6100

Communication between TEA6100 and the microcomputer is via a two wire bidirectional I²C bus. The power supply lines are fully isolated to avoid cross talk between the digital and analogue parts of the circuit.

TEA6100

Notes

1. All characteristics are measured from the circuit shown in Fig.16.
2. Conditions for this parameter are:
 $20 \log V_{o(FM)}$; $m = 0,3$ or $20 \log V_{o(AM)}$; $m = 0,3$.
3. Voltage source followed by diode and resistor.
4. A DC shift can be achieved by connecting a $1,8 \text{ M}\Omega$ resistor between pin 4 and pin 15.
5. Step size between trip levels:
 $(V_{TH} - V_{TL}) / 6 \pm 0,07 \text{ V}$.
6. V/dec = voltage per decade.

PROGRAMMING INFORMATION

Converting the read out of the counters into frequency

The counter resolution at the input is defined as:

- resolution = divider ratio of N2/window

For every increment of the counter the counted frequency increases relative to the resolution in Hertz, as shown in example:

- window = 20 ms; N2 = 128; IF frequency = 10,7 MHz; resolution = $128/0,02 = 6,4$ kHz per count

The counter consists of 8 bits. Therefore, the maximum frequency range that can be counted is $256 \times \text{resolution} = 1,6384$ MHz. In the example the frequency to be counted is 10,7 MHz, therefore, the counter will overflow (in the example above, 7 times). The real measured frequency is:

- $f_{\text{real}} = (\text{read out} + \text{overflow} \times 256) \times \text{resolution}$

The overflow indicates the off-set on the frequency scale which must be added to the read out. Due to the bandwidth of the IF filter, the frequencies at the input to the TEA6100 are known, for example:

- IF filter for FM has a center frequency of 10,7 MHz and -3 dB bandwidth of 300 kHz. Only the frequencies of 10,7 MHz ± 150 kHz occur at the input of the TEA6100. For this reason it is not necessary to count the overflow.

The read out of the counter has to be translated into frequency. This translation depends upon the counter resolution. The preferred way to calculate the input frequency is to:

- calculate the read out of the target IF frequency. Compare this value with that of the measured read out and multiply the difference by the resolution.

The formulae for calculating the target IF read out and the resolution are as follows (A, D, E, F and G refer to the bits of the I²C bus input data as shown in Fig.3 and 4 and to the counter/timer block diagram shown in Fig.6. An, Dn, En, Fn and Gn are inverted values of the variables A, D, E, F and G. Table 3 shows the following formulae calculated for a reference frequency of 40 kHz):

- $N1 = (An \times 4 + A \times 5) \times (En \times 4 + E \times 5) \times 8 \times (2^{[E \times 2 + G \times 1]}) \times (F \times 1 + Fn \times 8)$
- Window (T) = $N1/F_{\text{ref}}$
- $N2 = (E \times 16 \times 8 + En \times [Dn \times 1 + D \times 16]) \times (G \times 2 + Gn \times 1)$
- Target decimal read out (TDEC) = $T \times (\text{TIFF}/N2 + (E \times 247 + En \times 79))$. TIFF is the symbol for target IF frequency
- Target read out hexadecimal (THEX), convert the target decimal read out to hexadecimal and use the 2 least significant digits (Do not use overflow value). The symbol for measured hexadecimal is MHEX
- Resolution (R) = $N2/T$
- Measured frequency (F_1) = $(\text{TIFF}) + R \times (\text{MHEX} - \text{THEX})$.

Note

Care should be taken if $\text{TIFF} + \frac{1}{2}$ filter bandwidth is greater than the frequency for the read out of hexadecimal value FF, or if $\text{TIFF} - \frac{1}{2}$ filter bandwidth is less than the frequency at read out for hexadecimal value 00.

- Counter accuracy (AW and AN), with bit 7 (G) the accuracy can be chosen with the same resolution. If bit 7 is logic 1 the accuracy is HIGH and if bit 7 is logic 0 then the accuracy is LOW.

bit 7 = 0, AN = $\pm (N2/T)$

bit 7 = 1, AW = $\pm (\frac{1}{2} \times N2/T)$

tuning interface**

TEA6100

Example

The example uses the following values:

TIFF = 10,7 MHz; accuracy = LOW (G = 0); F_{ref} = 40 kHz (A = 1); IF frequency = 10,7 MHz (D = 1); resolution = N1 (F = 1) and counter mode = FM (E = 1)

$$N1 = (0 \times 4 + 1 \times 5) \times (0 \times 4 + 1 \times 5) \times 8 \times (2^{[1 \times 2 + 0 \times 1]}) \times (1 \times 1 + 0 \times 8) = 800$$

$$T = 800/40 = 20 \text{ ms}$$

$$N2 = (1 \times 16 \times 8 + 0 \times [1 \times 1 + 0 \times 16]) \times (0 \times 2 + 1 \times 1) = 128$$

$$TDEC = 20 \times 10,7/128 + (1 \times 247 + 0 \times 79) = 1919$$

THEX; 1919 is hexadecimal 77F and the least significant 2 digits are 7F, so THEX = 7 F

$$R = 128/20 = 6400 \text{ Hz/count}$$

Assume the readout is '6E', the measured frequency will be:

- $F_1 = 10,7 + (6E - 7F) \times 6400 = 10,59 \text{ MHz}$

Assume the readout is '83', the measured frequency will be:

- $F_1 = 10,7 + (83 - 7F) \times 6400 = 10,726$

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "IC Package Databook" (order code 9398 652 90011).

Soldering by dipping or by wave

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact

with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ($T_{stg\ max}$). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

Repairing soldered joints

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

DEFINITIONS

Data sheet status	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
Limiting values	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
Application information	
Where application information is given, it is advisory and does not form part of the specification.	

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.

PURCHASE OF PHILIPS I²C COMPONENTS

Purchase of Philips I²C components conveys a license under the Philips' I²C patent to use the components in the I²C system provided the system conforms to the I²C specification defined by Philips. This specification can be ordered using the code 9398 393 40011.
